3

4

The toxins

- **Maitotoxins and Ciguatoxins**
- A class of lipid polyether compounds with low molecular weight.
- Clinical symptoms: gastrointestinal, neurological and cardiovascular. Recovery could take months to years.
- **At present, there is no easy method to routinely measure the toxins.**
- **No antidote of CFP.**
- Under-diagnosed, due to limitation in toxin analysis laboratory.

5

Live reef food fish trading: *Problem of ciguatera and its impacts*

Increase in demand for live reef fishes from SEA and Indo-Pacific regions has resulted in occurrence of **ciguatera** cases in areas far from the origin (Chen 2015).

2001: Malaysia supplied 10,000MT of live wild catch groupers.

Live fishes from Sabah have been reported to cause CFP in Hong Kong (Sadovy, 1997, 2001).

CFP Outbreaks in Hong Kong

Hong Kong: Ciguatera outbreak sickens 19 who ate at a Lamma Island seafood restaurant

The Hong Kong Centre for Health Protection (CHP) of the Department of Health is investigating a suspected ciguatera poisoning case affecting 19 people who consumed a meal and fish according to a press release Monday.

Ciguatera fish poisoning sickens 15 in Saipan, consumption of barracuda implicated

Fourteen other people were diagnosed with ciguatera fish poisoning in the village of Saipan on Saipan, in the Northern Mariana Islands, according to a local health report.

Ciguatera cluster investigated in Hong Kong

The Hong Kong Centre for Health Protection (CHP) of the Department of Health is investigating a suspected ciguatera case poisoning seven people from a restaurant.

Three cases involving four females aged 30 to 45 in the New Territories developed a high case of ciguatera poisoning following by sea food consumption, including barracuda, at a restaurant in the New Territories on April 11.

A further research developed involving 12 people from the same area during the...

Malaysia: 2010 CFP Outbreak

22 (5 families) felt sick after consuming the red snapper on Sept 8, 2010; 11 were admitted to hospital.

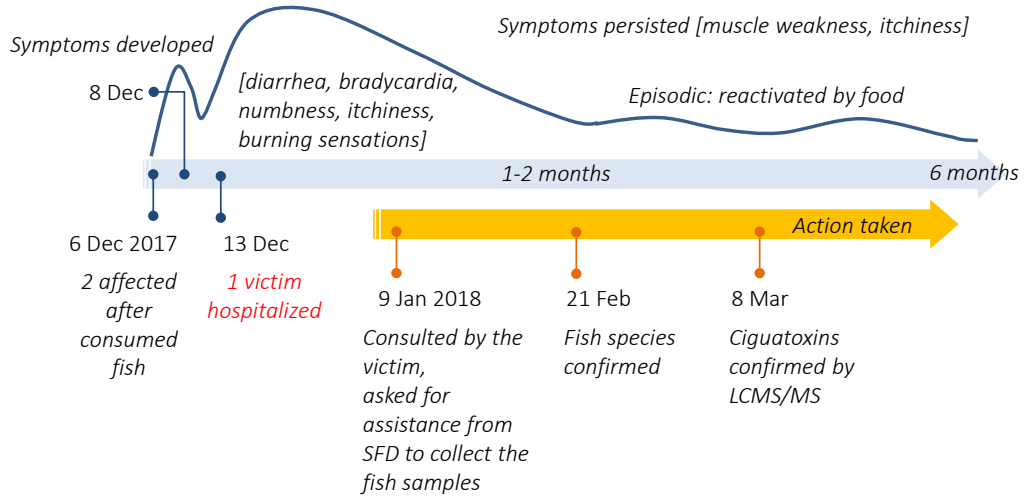

Contaminated fish were bought from Jeli, which was bought from Far Frozen Fish Sdn Bhd, Pasir Puteh (red snapper, Batch no MRH-5000 25kg)

Climate change and Benthic HABs

Global SST increases of 0.4–1.4°C by 2055 will promote growth rates of many BHABs (Tester et al. 2020).

Northward expansion of BHABs and CFP events.

In May 2017, a family of seven living near Adelaide, Australia, went to the hospital after one member of the household cleaned the family's tropical saltwater aquarium. The person reportedly removed and crushed some rocks or corals from the tank, presumably to remove unwanted, unsightly growths. This cleanup triggered the release of aerosolized polytoxins that caused everyone to struggle to breathe.

ARCHIVED - Toxic algal blooms likely to become increasing problem in Mediterranean as climate change warms the planet

Ostreopsis microalgae blooms have been called "the mother of all plagues".

The Spanish tourist industry is one of the sectors of the national economy which has been most dramatically affected by the coronavirus pandemic, but while there are hopes that progress can soon be made towards reactivating the sector another threat is being reported which could prove even more difficult to counter.

11

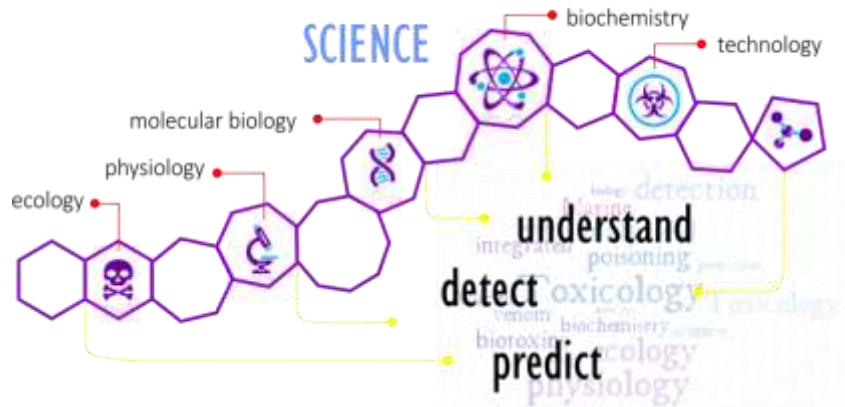

BHAB species generally occur at various bottom substrata, but dominating specific habitats with different ecological optima (i.e. temperature, light, nutrients etc.).

12

RESEARCH in BHABs

INTEGRATIVE SCIENCE

how fine-scale difference in substrates affects the distribution and abundance of BHABs, and by inference the local risk of toxicity

13

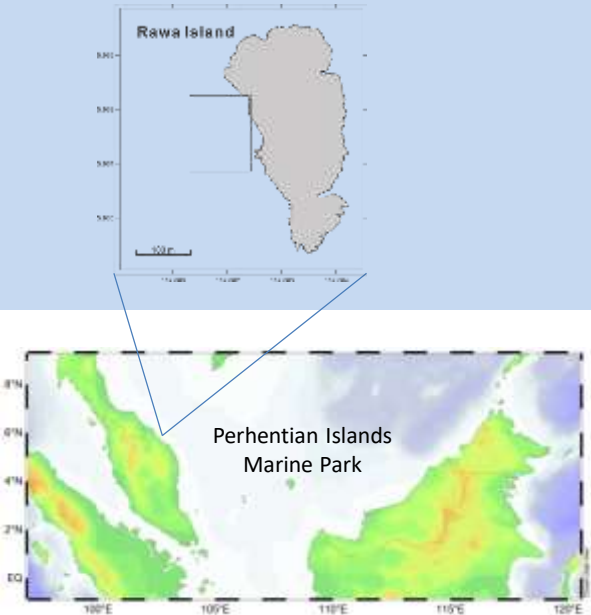

Aim

To demonstrate an alternative sampling approach for BHAB studies,
 To establish spatial and temporal patterns of BHAB assemblages and the associated environmental variables,
 To assess the effect of reef degradation on BHAB communities.

14

Study site

The figure consists of two maps. The top map shows the outline of Rawa Island with a 100m scale bar and latitude/longitude markings. The bottom map is a bathymetric chart of the Perhentian Islands Marine Park, showing depth contours from 0m to 8m. A blue silhouette of a diver is positioned to the left of the maps.

A photograph showing a vibrant coral reef flat with various species of coral and numerous small, colorful fish swimming in the clear blue water.

A reef flat of 100 × 180 m, 3 m depth.

April 2015- Jan 2016

15

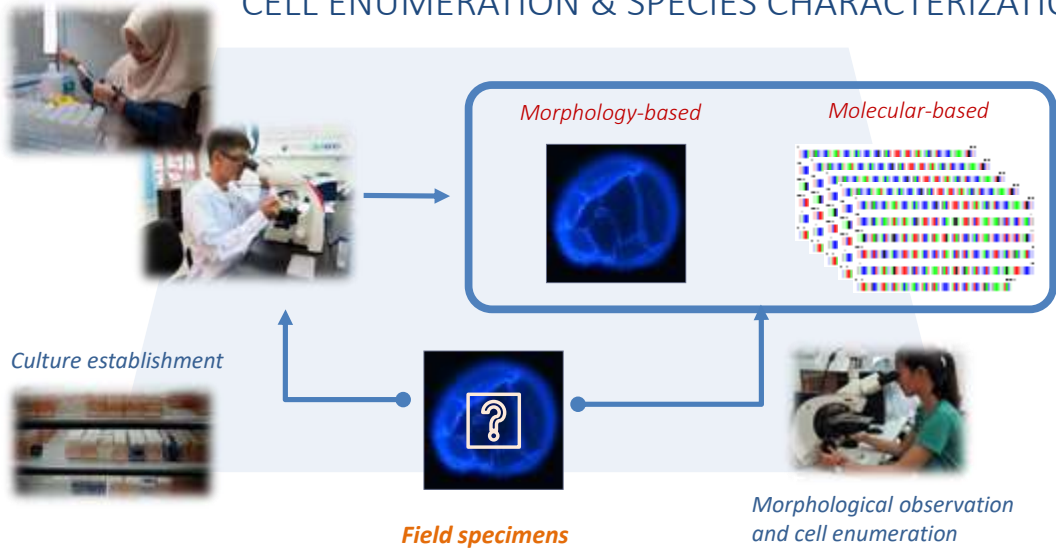

Non-destructive sampling approach
(Tester et al. 2012, 2014; Tan et al. 2013; Yong et al. 2018)

The main image shows a diver in full gear kneeling on a sandy seabed, carefully handling a sample in a clear container. An inset image in the bottom left corner shows a close-up of a diver's hands using a white mesh bag to collect a sample from a coral reef structure.

19

Implication in CFP risk assessment

The data obtained with this method can be used to establish a baseline in assessing the risk of CFP.

Because Rawa Island has not experienced a CFP event, it is suggested that *Gambierdiscus* abundance <1000 cells/100 cm² may serve as the lowest threshold, i.e. low risk of CFP.

While regulatory decisions to limit or close fishing are not based on cell abundances of *Gambierdiscus*, these dataset suggests that CFP risk is low when cell abundances are consistently below <1000 cells/100 cm².

Yong et al., 2018; Lee et al., 2020.

20

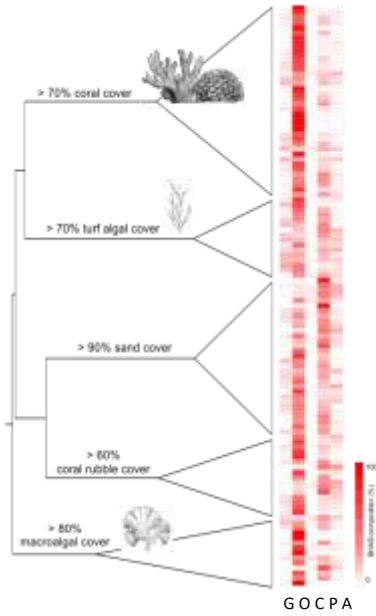

Reef microhabitats play an important role in structuring the benthic harmful dinoflagellate communities, but there are few that provide statistically robust studies with well-defined **habitat characterization**.

An **underwater photoquadrat survey** was performed simultaneously at each sampling point to record the percent coverage and variety of benthic substratum and the biotic inhabitants.

21

22

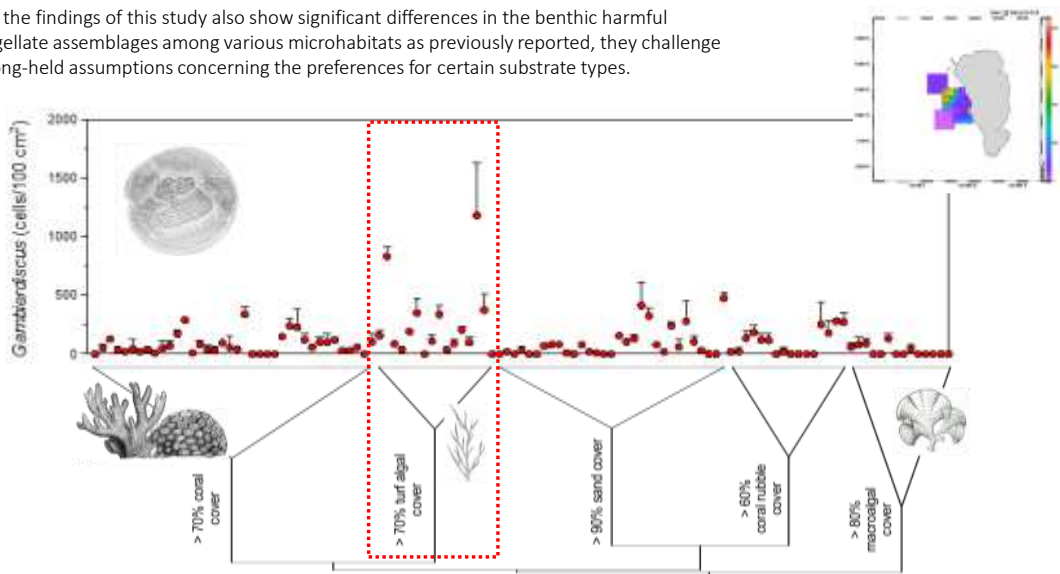

Microalgae-habitat interactions

23

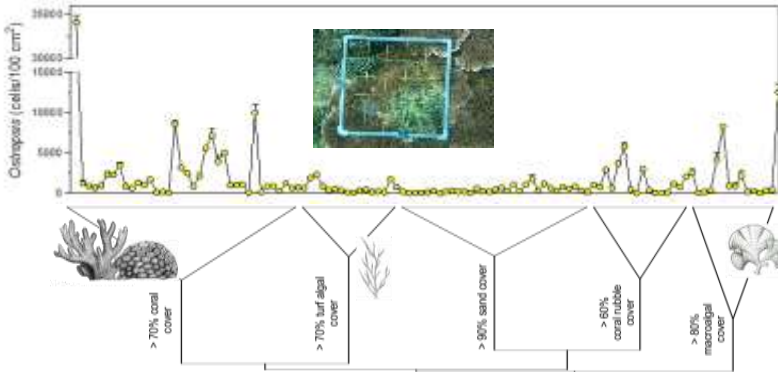

Microhabitat heterogeneity affects the BHAB assemblages

Though the findings of this study also show significant differences in the benthic harmful dinoflagellate assemblages among various microhabitats as previously reported, they challenge some long-held assumptions concerning the preferences for certain substrate types.

24

In contrast, *Ostreopsis* did not show the same substrate preferences as *Gambierdiscus*. It was found on nearly all substrate types, but maximum cell abundance was detected in **microhabitats with high coral cover**, and to a lesser extent, high filamentous algal cover.

Ostreopsis is known as an **opportunistic** group adapted to broad ranges of environmental conditions (Tindall and Morton, 1998; Vila et al., 2001).

25

26

Study site

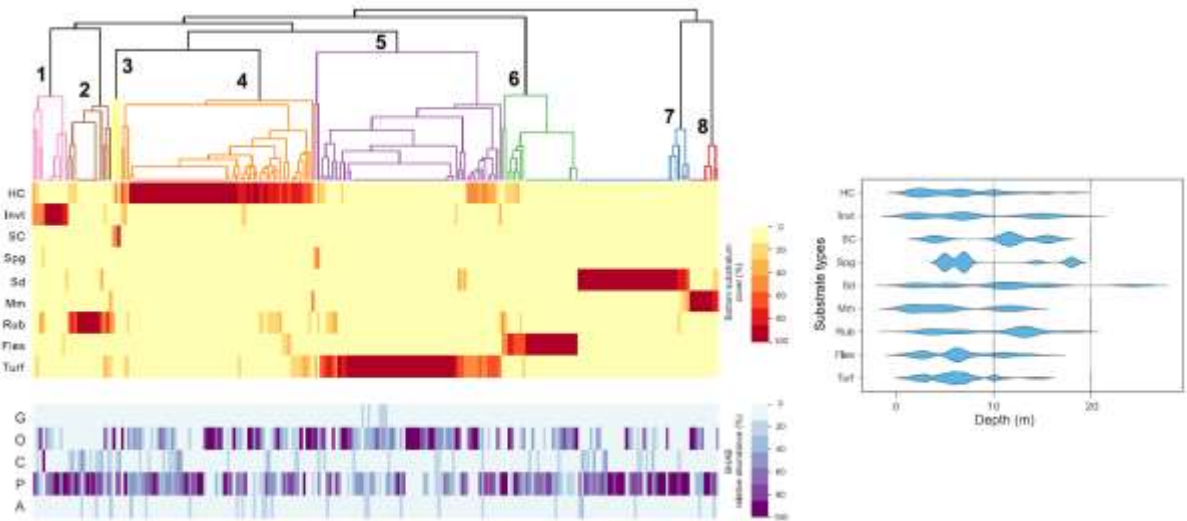

Reefs cover different depths (1 - 25 m).

Total screen samplers deployed = 234

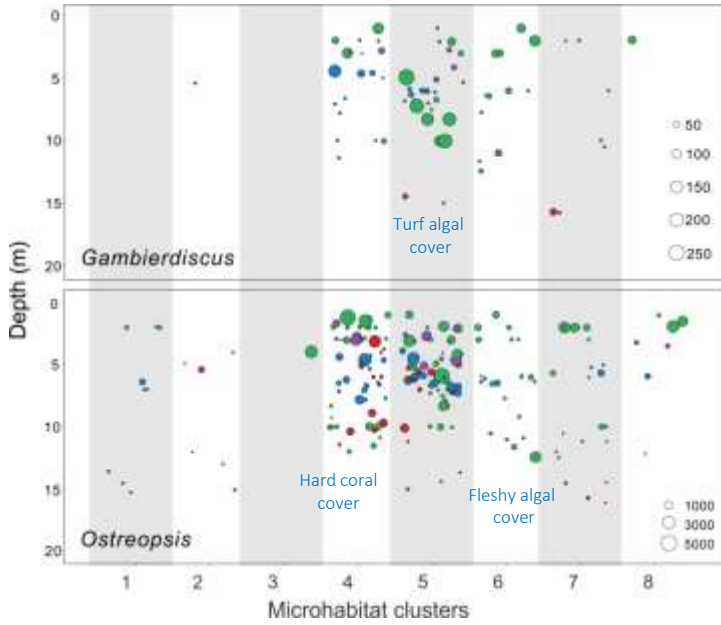

April 2016 - May 2017

27

BENTHIC MICROHABITAT CHARACTERIZATION

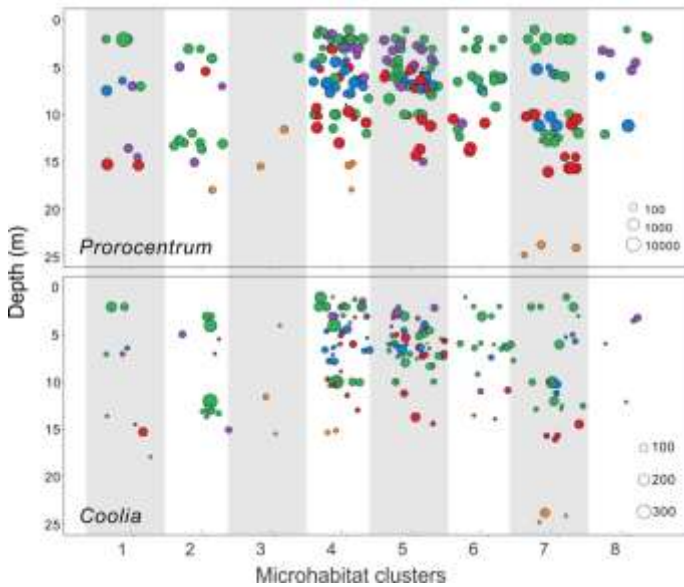

28

Depth distribution of BHAB assemblages

29

Prorocentrum and *Coolia* have a broader range of depth distribution, can be found in deeper waters.

This suggested that, depending on the substrate suitability and availability, the variation in BHAB adaptability to different depth is likely influence by other driving factors such as light intensity and exposure to water disturbance.

30

Physical measurements of the temperature and light were obtained by deploying data loggers.

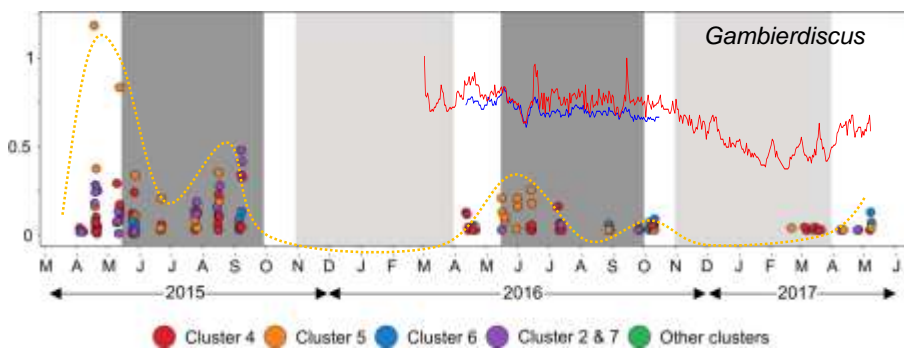

Seasonal variation in water temperature

31

Temporal variability

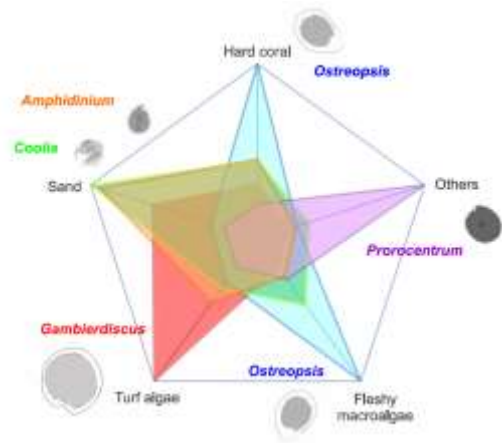

Changes in **temperature** and **associated climatic conditions** profoundly affect the abundance and distribution of species across microhabitat types.

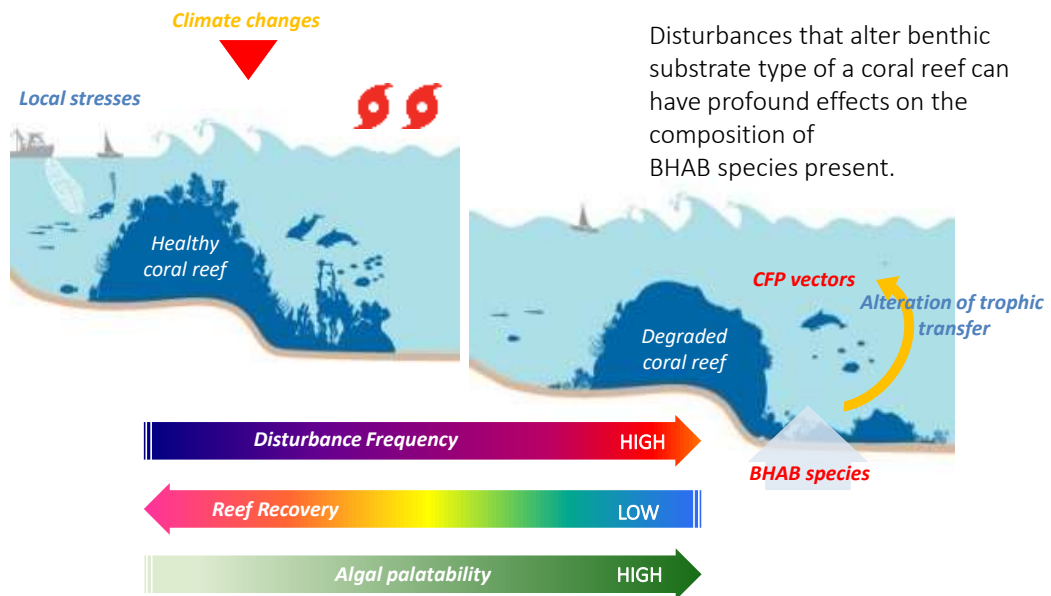

32

CONCLUDING REMARKS

- This study highlights the variability of benthic substrate types influence the distribution of BHAB taxa in complex ways that interact with other environmental driving factors.
- The artificial substrate method coupled with benthic habitat characterization could serve as an alternative tool to study *in situ* BHABs abundance and distribution.
- These datasets could serve as a basis for comparison and of consideration in BHAB monitoring strategy in CFP prone areas.

35

UN IPCC Special Report on the Ocean and Cryosphere in a Changing Climate (SROCC, September 2019) was the first IPCC report to directly link **HABs to climate change**.

The following declarations were included in the Summary for Policy Makers:

- Harmful algal blooms display range expansion and increased frequency in coastal areas since the 1980 in response to both climatic and non-climatic drivers such as increased riverine nutrients run-off.
- The observed trends in HABs are attributed partly to the effects of ocean warming, marine heatwaves, oxygen loss, eutrophication and pollution.
- Harmful algal blooms have had negative impacts on food security, tourism, local economy, and human health.
